Presentation of Embrapa Dairy Cattle

Resilience and overcoming challenges, two words that are very present in our daily lives and that must go hand in hand ... Farmer knows it like no one else! He overcomes the crisis, overcomes the pandemic and continues to produce food for society. Embrapa Dairy Cattle is proud to contribute to the livestock success and, together with the Centro Brasileiro de Melhoramento Genético do Guzerá - CBMG², delivers to society the 22nd edition of the Guzerá sires and dams summary.

This publication is a result of the successful and long-standing partnership between EGL-CBMG², which together since 1994 have been coordinating the National Breeding Program of Guzerá Cattle for Milk –PNMGuL. Similarly, there are many outstanding national and state research institutions, public and private companies focused on agriculture and several collaborating dairy herds to the progeny testing that contribute to the success of the PNMGuL.

This edition highlights the genetic merit of 765 bulls and 586 dams of the Guzerá breed by their milk EPD ranking, in addition to its composition (fat, protein and total solids yield and content), age at first calving, milk production efficiency and other 14 traits of economic relevance for milk production and dual-purpose systems.

Here, technicians and farmers have available an important tool for the continuous improvement of this animal genetic resource in the tropics.

Este anúncio é uma homenagem a esta palavra que sempre nos faz acreditar que juntos somos mais fortes.

O ano de 2020 começou com a sede do CBMG sendo assaltada, de onde foram levados equipamentos e muito da nossa história de dedicação ao Guzerá. Mas graças ao apoio e a ajuda de parceiros fiéis, conseguimos nos reestruturar para continuar o trabalho de melhoramento genético da raça. Então, fica aqui o nosso profundo agradecimento àqueles que nos apoiaram e acima de tudo confiam na seriedade e na qualidade do nosso trabalho.

Muito obrigado:

Evolution of Zootechnical Indexes of the National Breeding Program of Guzerá Cattle for Milk

*Maria Gabriela Campolina Diniz Peixoto - Embrapa Dairy Cattle
Frank Angelo Tomita Bruneli - Embrapa Dairy Cattle
Lenira El Faro Zadra - Instituto de Zootecnia de São Paulo*

A genetic improvement program, regardless of the species involved, requires continuous monitoring and evaluation of the advances obtained with its selection objectives, as well as of the structure and genetic diversity of the population. This monitoring permits to assess the path taken and to outline new projects for the future. Therefore, we, the technicians involved, are always keeping an eye on the population.

What is the current situation of the genetic variability of the Guzera herds?

To answer this question, we use many tools and indexes that allow us to assess how the population is doing: if there is much consanguineous mating (inbreeding) and substantial circulation or introduction of animals (migration), and if some families are being privileged by selection, etc. This monitoring is called the study of the structure and genetic diversity of the population. The indexes commonly used for this monitoring are the inbreeding coefficient (popularly, consanguinity) and the average relatedness of the animals (which measures the intensity of use of a given animal in the population). These indexes permit to verify the degree of genetic variability, which is fundamental for the selection process since the absence of variation in a given trait of interest in a population suggests that its selection or genetic improvement is not possible.

What we have seen over these 25 years of the National Breeding Program of Guzerá Cattle for Milk (PNMGuL) is somewhat encouraging. Evaluation of the inbreeding coefficient revealed important events for the population under selection for milk production. Although the average population inbreeding coefficient (F_p) of this population varies over the years, its average value is 0.013 or 1.3%, oscillating between 1 and 2%, which is an acceptable level, showing only a minor increase (Figure 1). This fact reveals the breeder's concern in avoiding mating between related individuals. Figure 1 also shows the impact of the release of the first sire summary in 2000 (arrow), which resulted in an expressive reduction of F_p in 2003 and 2004. The opportunity given to breeders to use animals from other farms based on accurate information about the genetic merit of the animals probably contributed to the birth of less inbred (consanguineous) animals during this period. It's so refreshing!

In Figure 1, we can observe the trend of the average inbreeding coefficients (dotted line) only for inbred individuals (F_e). The average inbreeding coefficient for this group of animals throughout the period was estimated at 3%, a value that is within acceptable limits. In addition, there was a trend towards F_e decreasing significantly every year. This result again encouraged program and herd leaders since, although the frequency of inbred individuals has increased in this population (reaching 464 inbred animals in 2010), the trend is that mating of closely related individuals (inbreeding or consanguinity) is avoided.

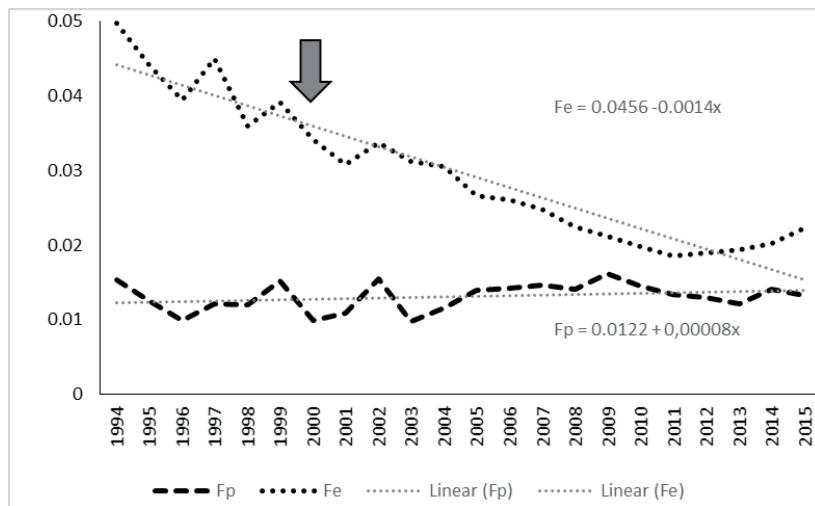

Figure 1. Trend of population (F_p) and individual (F_e) inbreeding coefficients in Guzera herds throughout the breeding program for milk production. The arrow indicates the year when the first sire summary was published.

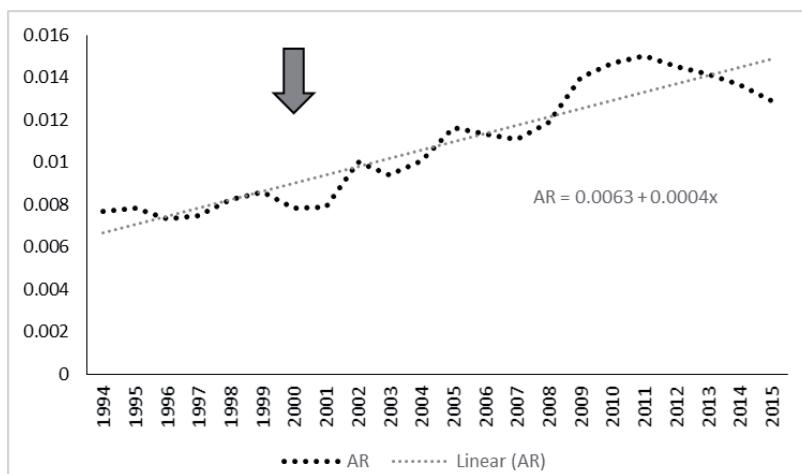

Figure 2. Trend of the average relatedness coefficient (AR) of the population in the Guzera herds throughout the breeding program for milk production. The arrow indicates the year when the first sire summary was published.

It is also interesting to note that during the 20 generations detected in the genealogical data, only 0.02% of matings occurred between full-sibs and 1.18% between half-sibs. However, the effective size of the base or founder population (342 animals) that considers only the number of different genomes that contributed to its formation reveals that caution in conducting the matings must continue since the genetic basis of this population is narrow.

When we evaluate the average relatedness coefficient (which reflects the intense use of some animals in the population) over the years (Figure 2), we can clearly note how individuals from a few families are intensely disseminated in the population; hence, there are many relatives of the same or of few animals in the different herds.

This result will be a matter of concern in the coming years since it indicates the risk of bottlenecks, i.e., losses in the contribution of some families to the next generation and the consequent loss of genetic variability (which is fundamental for genetic improvement) and increased likelihood of mating between related individuals (with possible reductions in survival and fertility).

Furthermore, there are a range of traits that have not yet been addressed by breeding programs and that could be targets of selection in the future. Losses of genetic variability in these traits may be occurring if some are genetically correlated with the traits under current selection, i.e., if genes that influence the current selection targets also have an unfavorable influence on future targets of selec-

tion. This may indicate the impossibility of future selection for these traits in a scenario in which they become relevant for the production system.

Now let us take a look at the traits under selection.

Milk yield is the main trait selected in dairy cattle herds in Brazil. Evaluation of milk yield at 305 days of lactation (MY305) shows an annual increase of approximately 50 kg of milk (Figure 3).

This trend (dotted line) was also observed for the average EPDs (or predicted transmitting ability, which has the same meaning) of this trait, with an increase of about 7 kg of milk per year. We can therefore conclude that the herds participating in the PNMGuL have obtained positive genetic and phenotypic progress. The trends shown in this figure reveal that part of this advance was due to genetic improvement, although more expressive gains could be achieved if a higher selection intensity were employed. The breeding objective of a large part of these herds is dual purpose, a fact that contributes to the result obtained since the larger the number of traits in the selection objectives, considering that the traits of interest are not favorably correlated, the smaller the gains in each of them. The selection objectives must be well chosen, always keeping an eye on the conditions of the production system, the market, and the economic return.

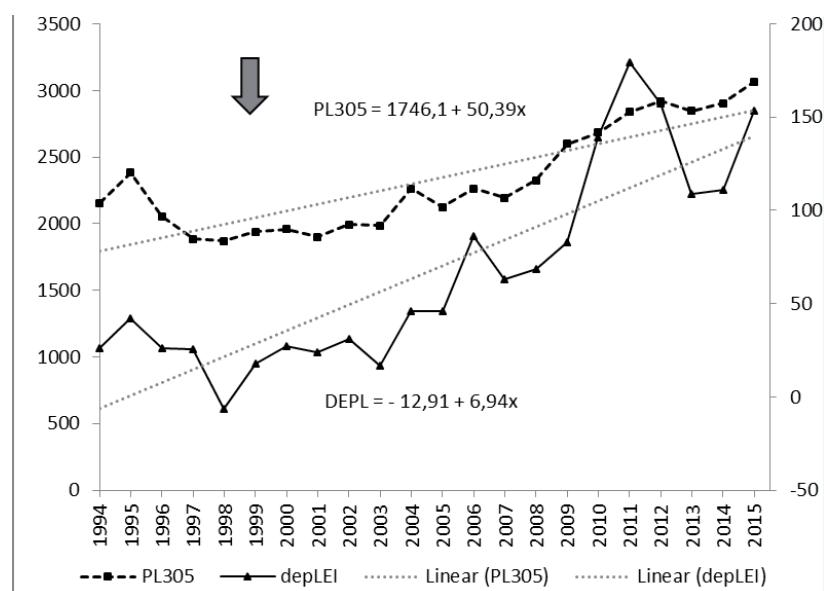

Figure 3. Trend of average EPDs (kg) of Guzera cows for milk yield throughout the National Breeding Program of Guzera Cattle for Milk. The arrow indicates the year when the first sire summary was published.

Although milk yield continues to be the main selected traits, it can be observed that, except for fat yield (-1.34 kg per year), the phenotypic trend, although small, was positive for the yield of protein (250 g per year) and total solids (100 g per year) (Figures 4, 5 and 6).

However, when we evaluate the genetic progress, there is a positive genetic trend for all milk components (dotted line). Genetic gains of 240, 180 and 730 g were estimated for fat, protein and total solid yield, respectively. The advances in these components are probably due to their positive correlation with milk yield, i.e., they are influenced by the same genes as milk yield, the target trait of selection. Thus, there is the potential for the production of these components and good management, health and nutrition conditions of the animals are necessary for its expression, especially because the effect of the environment is very important for the expression of the desired phenotypes of dairy traits.

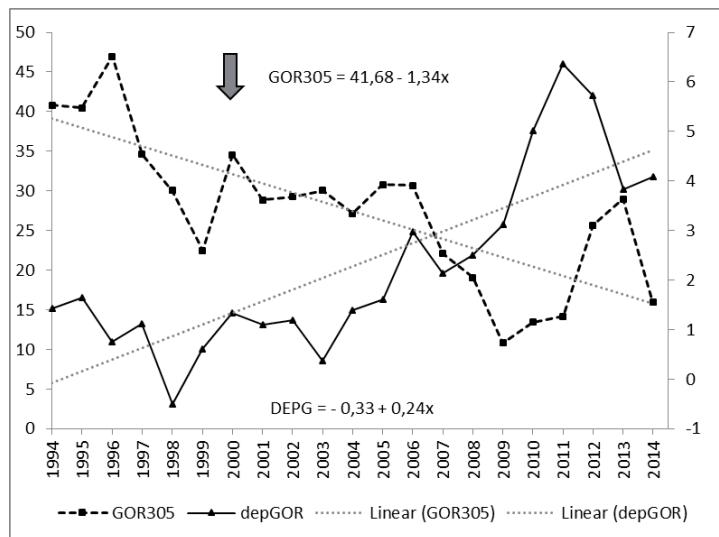

Figure 4. Trend of average EPDs (kg) of Guzera cows for fat yield throughout the National Breeding Program of Guzerá Cattle for Milk. The arrow indicates the year when the first sire summary was published.

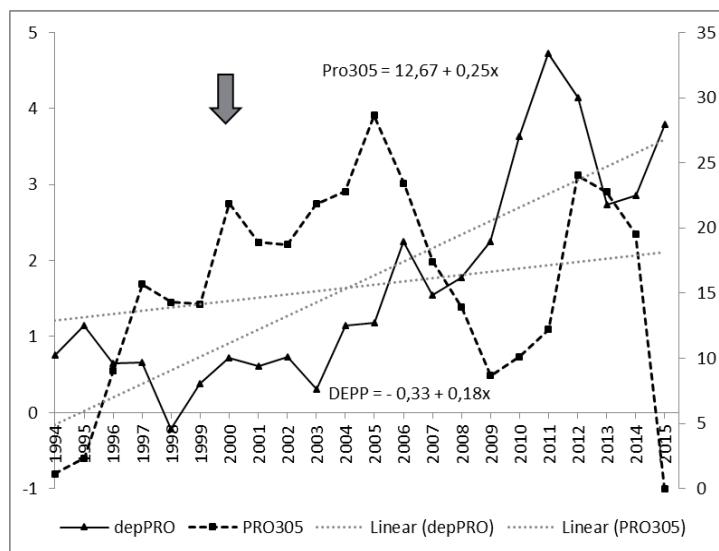

Figure 5. Trend of average EPDs (kg) of Guzera cows for protein yield throughout the National Breeding Program of Guzerá Cattle for Milk. The arrow indicates the year when the first sire summary was published.

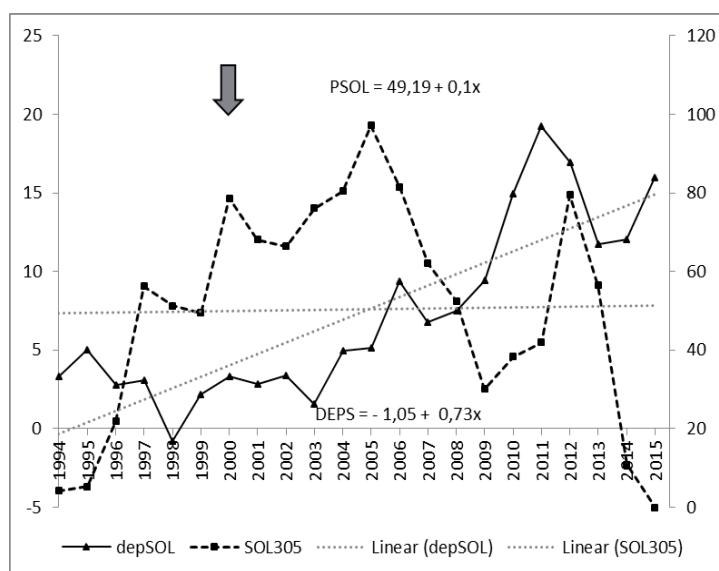

Figure 6. Trend of average EPDs (kg) of Guzera cows for total solid yield throughout the National Breeding Program of Guzerá Cattle for Milk. The arrow indicates the year when the first sire summary was published.

Despite these indirect advances, we should reflect on the selection objectives defined for the Guzera breed. The dairy farming scenario started to change in recent years. The industry is now considering the quality of the milk it buys from the producer and consumers are increasingly concerned about what they eat. Is it not time to review the selection objectives of dairy Guzera herds? Volume is important but the yield or content of milk components, as well as the somatic cell count (SCC) that reflects the health of the mammary gland, are becoming more important every day. Why? Because the dairy industry wants to be more efficient in producing milk products and in meeting consumer demands. Therefore, focusing selection decisions on these traits is necessary, even strategic, in dairy herds in order to achieve better product prices and greater profitability of the activity. Regarding the perspective of including SCC in genetic evaluations, like for milk components, it is necessary to increase the information available in the PNMGuL database. This requires the participation and commitment of all parties involved, which should send test-day milk samples to the laboratories for the analysis of milk components and SCC.

Figure 7 shows the phenotypic and genetic trends for age at first calving (AFC). This trait was recently included in the summary and reflects the productive precocity of the animals, which is of great economic importance. Breeding animals with more sexual precocity provides faster return on investment. Although recent, advances occurred in the phenotypic means of this trait, which have declined expressively (-40 days per year) over the years of PNMGuL. This result largely reflects the efforts of breeders in promoting changes in the environment, including health and nutrition actions as well as the use of modern reproduction technologies. Indirectly, although not the target of selection, a genetic change also occurred in the herd that may even be greater from now on because of the availability of the genetic merit of the animals for this trait in the summary. The peak years when AFC increased generally correspond to years of feed shortage due to prolonged and intense dry periods. We also included productive efficiency, which associates milk yield and precocity, as another trait in the last summary (2018) for the combined improvement of these traits. However, the time was not sufficient to evaluate its trend.

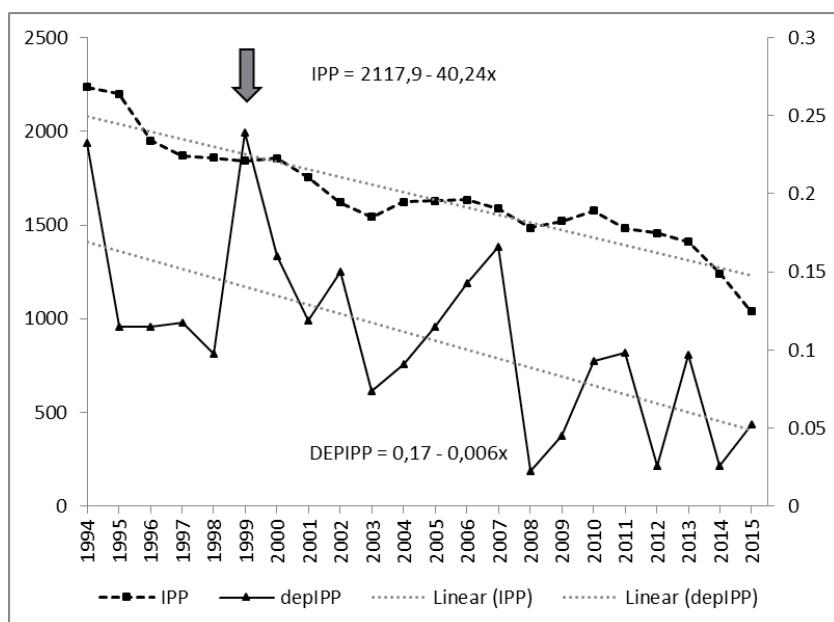

Figure 7. Trend of average EPDs (kg) of Guzera cows for age at first calving throughout the National Breeding Program of Guzerá Cattle for Milk. The arrow indicates the year when the first sire summary was published.

Where are we heading? What do we need?

We will now comment on the direction to be taken in the PNMGuL. We need to obtain quantitative and qualitative measurements, i.e., accuracy. We need to evolve, or resume, the measurements of the linear system, focusing on functional morphological traits that will allow animals to produce efficiently, an initiative that was started but was lost over time. Our registry needs to assume and commit to this task. Research also needs to identify new phenotypes (traits of interest) and the joint project should start to check them (phenotyping) in order to establish their potential for improvement and for the definition of the most appropriate criterion for their selection. We will thus be preparing to face the future demands of the herds, the industry, and the consumer.

One example of a trait that could be included in the official milk recording system is the body condition score of cows during their lactation, or at least up to 90 days of lactation. Its measurement is easy and inexpensive and the trait can be easily included in the official milk recording system, along with other functional traits. Changes in the body condition score of cows at the beginning of lactation may be associated with a negative energy balance, which occurs in animals with high production levels but with inadequate energy intake. If very severe, a negative energy balance results in production and fertility losses of dairy cows. A scoring system ranging from 1 (very thin) to 5 (very obese) may be easily used by test-day technicians after training of the team.

Taking advantage of what is already available, such as milk yield, we can use slightly more complex models in the evaluations that allow us to detail the environmental effects (management, nutrition) that are inherent to milk recording scheme. These models, called random regression models, are being adopted in many countries for genetic evaluations of productive traits in dairy cattle. Among other aspects, such models permit to increase the accuracy of the breeding values of animals for milk yield, as well as to model certain parameters related to the shape of the animals' lactation curve, such as lactation persistency, a trait widely studied in Zebu cattle. Because of their greater complexity, these models require a larger number of production records of the animals during milk recording scheme, as well as a more detailed description of the management conditions on each test-day milk recording (feeding, type of milking, calf death, cow diseases during milk recording scheme, etc.). These data can be included in the definitions of the contemporary groups, which are so important for genetic evaluations.

Furthermore, the implementation of a broad DNA database is necessary to take advantage of new molecular and genomic tools for the characterization of genotypes of interest (QTL). In addition, the application of statistical tools to genomic and genetic evaluations will ensure greater accuracy and, consequently, genetic gain in the populations under selection.

It continues to be our commitment, as researchers of PNMGuL, to provide the program with scientific tools that will allow its sustainable development, and permit breeders and milk producers to proceed with the efficient selection of their herd in response to market demands so that they will be able to maintain this very important activity.

An adapted breed is an asset. It is a heritage conquered by animals in the environment in which they evolved and by the daily effort of many breeders, over generations. Part of this value comes from how well a breed is scientifically known. The 26 years of the program developed by the Brazilian Center for Genetic Improvement of Guzerá (CBMG²), with Progeny Testing, the MOET Nucleus and genetic evaluations, brought the Guzerá breed to a new production level. Today, it is possible to select for the purpose of the animals in your herd using genetic information and, soon, genomic tools.

It has been an honor to participate in this effort. Here, we will highlight some of the work developed in the Guzerá research and discuss some of the future perspectives.

Molecular Genetic Studies

Milk for the human health

Over the past few decades, the consumption of milk and dairy products has been the subject of many questions, generating wide debates and a new research agenda. Two aspects have been investigated when talking about milk for human health: proteins and the fatty acid profile.

Proteins

Although milk and its derivatives are important sources of protein in our diet, the association of milk with autoimmune diseases has been described in the medical literature. In particular, a variant of beta-casein has been implicated in these conditions. There is an allele (that is, a genetic variant) that is considered healthy (the beta-casein A2 allele). The other beta-casein alleles are collectively called "A1" and give rise to a degradation product, BCM-7 (beta-caseomorphine 7), which crosses the gut barriers to blood and from the blood to the brain, what would cause autoimmune reactions. A2 milk does not give rise to BCM7. Digestion of beta-casein A2 is therefore easier. Some cows naturally produce A2 milk. The good news is that most Guzerá animals produce A2 milk.

In addition to beta-casein, there are many other important proteins in cow's milk and these proteins also have genetic variants that can cause reactions in the human body or affect milk production. We are using data from the complete sequencing of the Guzerá genome to discover the typical variants of the breed in the various proteins that make up milk.

We analyzed seven genes, which encode the main milk proteins: beta-casein (CSN2), kappa-casein (CSN3), alpha-S1 casein (CSN1S1), alpha-S2 casein (CSN1S2), alpha-lactalbumin (LALBA), lactoferrin (LTF) and beta-lactoglobulin (LGB). The LALBA protein is one of the proteins responsible for the synthesis of lactose. LTF is a protein present in various fluids besides milk, such as tears, saliva, seminal plasma, and nasal discharge. It is a highly interesting protein, as it has antimicrobial, anti-inflammatory, antibacterial, antiviral, antifungal, antiparasitic and anticancer activities. There

are studies associating LTF with resistance to mastitis. In milk, LTF is part of the immune protection system transmitted by the cow to the calf through the colostrum and milk.

Among the seven genes listed above, we found out 13 genetic variants, which may have repercussions or functional impact. Of these variants, two affect LALBA and LTF proteins, one in each gene. Now, we need to investigate whether these variants actually affect milk production or composition. Initially, we will investigate the association of variants in the LTF gene _ some discovered by us and some from the literature_ with traits of Guzerá milk production. For this study, production data and individual milk samples were collected and we have already developed a method to genotype the variants. We will have news on these topics soon.

Fats

For decades, milk and milk products have been unfairly criticized because they contain a high content of saturated fats. However, fats, including saturated fats and the so-called cholesterol, play quite a number of important roles in our body. Cholesterol, for example, is so important that our own body produces it. Without cholesterol, it would not be possible, for example, to synthesize vitamin D, steroid hormones, important for reproduction, and bile acids. In fact, cholesterol and other classes of fats are present in the membranes of all our cells. Our brain is composed mainly of fats. A very important class of fats is fatty acids. They are molecules that, in addition to providing energy (2 times more than carbohydrates and proteins), regulate a series of metabolic functions through the modulation or control of gene expression; an area of knowledge known as nutrigenomics. In addition, the generation of energy from fatty acids causes less damage to the cells than that obtained from carbohydrates (sugars). Some fatty acids also modulate the immune system, exerting anti-inflammatory action as in the case of omega-3 fatty acids. Milk and dairy products with regular levels of fat, such as whole milk, cheeses and butter provide numerous biologically active fatty acids, which have properties beneficial to health, some not found in appreciable quantities or even absent in other dietary sources, as in the case of acid conjugated linoleic acid (CLA) and butyric acid, respectively.

Although milk fat is in fact a significant source of saturated fatty acids in the human diet, increasing evidence indicates that eating dairy products with regular levels of fat is not associated with an increased risk of cardiovascular disease, and may further reduce the risk of obesity and type 2 diabetes. The fatty acid profile of milk (proportion of different fatty acids in the fat) varies mainly depending on the diet provided to the animals, but there is also considerable variation between animals, consuming the same diet, due to its genetic origin. This individual variation has been extensively studied in Taurine dairy breeds, but very little is known about this issue in Zebu breeds. On this issue, studies conducted by our research group have sought to answer some questions:

Is there an individual variation in the fatty acid profile of the milk of Guzerá cows? A pilot study has shown us that it is true, and that this variation is considerable for some fatty acids of interest to human and animal health. What are the genetic bases behind these individual variations? Recently, a study with a large number of Guzerá cows from different Brazilian herds allowed us to identify genetic variants in key genes of the lipids metabolism, some of them already described in the literature and some new ones. This information may be incorporated into the selection and improvement programs of the Guzerá breed in the future, aiming at the production of milk with high nutraceutical value, that is, value for human health. These promising results will be available soon. In addition, an association study on a genomic scale (that is, another GWAS – Genome-Wide Association Study) will be developed to find out which genes influence these traits.

Probiotics in Guzerá milk

The use of beneficial or probiotic bacteria has become a common practice in human and animal nutrition. More than this, these healthy microorganisms are powerful allies in the prevention and treatment of many diseases that affect human and farm animals' health. In recent years, it has been shown that there is a diversity of bacteria in the udder of cows, which end up being excreted in milk. These bacteria are important for both the development of the calf and for the processing of dairy products. Some of these bacteria appear to have promising effects in combating other disease-causing bacteria, particularly mastitis. The good news is that, in animals of the Guzerá breed, we have been able to isolate several beneficial bacterial strains, such as *Lactobacillus* and *Lactococcus*, which seem to protect the udder of these animals from the attack of these vile bacteria. The presence of these probiotics helps to explain the low rate of mastitis observed in the Guzerá breed, as well as the low means of somatic cell counts (SCC) found in the Guzerá herds. It is worth remembering that SCC values are directly related to the occurrence of subclinical mastitis, which causes enormous economic losses to the milk chain.

The temperament

Among other issues, we investigated the genetic component of reactivity (a component of temperament) in Guzerá. We developed a GWAS, which allowed us to identify a region in the genome associated with reactivity in Guzerá. In this region is the dopamine 3 receptor (DRD3) gene, which encodes a protein expressed in the central nervous system. In humans, it was already known that this gene is associated with temperament traits and the results found in Guzerá make a lot of sense. In order to continue this study, we need to sequence a larger number of individuals, whose temperament has been assessed, in the search for the variants that cause the most nervous temperament. Here, it is important to note that, if this gene is involved in the reactivity of Guzerá and humans, it can also contribute to this trait in other breeds. This study then proceeds.

(Re)telling the story of Guzerá

As for many other breeds, there are some tales about Guzerá evolution in Brazil. In conversations with the Guzerá breeders, it is frequently heard that a relatively small number of animals were brought from India to Brazil, and that there were some specific moments when the number of pure-bred animals decreased, due to their contribution to the creation of crossbreds or other breeds. This brought up the question about the genetic diversity in Guzerá. In fact, this is a very common question in studies about any breed and also about wildlife animals.

When sampling livestock animals in the field, it is not known whether the animals collected are related, or how closely related they are. The collection of related individuals gives the impression that genetic diversity is less than it actually is. Using data from Guzerá SNPs, we have developed a method to correct this problem. The method worked very well. How we know? We managed to recover the moments in which, according to the breeders' reports, there was a reduction in genetic diversity. In other words, those Guzerá stories are not folklore, they are history!

As a result, this article was published in one of the most important journals in the area of Ecology and Biodiversity Conservation. Therefore, it is not Science helping Guzerá, it is Guzerá helping Science. Great, isn't it?

And after all, what about the genetic diversity of Guzerá? Correcting for the presence of close relatives in the samples, Guzerá breed conserved a good amount of genetic diversity. Genetic diversity

is the best guarantee that a breed can have to go through prolonged droughts, emerging viruses or other forms of environmental stress.

Therefore, molecular research in Guzerá continues. These results reflect the efforts of many students and researchers. They also reflect the support of funding agencies, such as CAPES, CNPq and, mainly, FAPEMIG. However, nothing would have been achieved without the support of CBMG² and the breeders. Thank you very much.

Any trait that can be evaluated is called a phenotype. Phenotypes can be qualitative or quantitative. Qualitative are the traits that are described with adjectives, such as the shape of the horns (ex: in lyre) or coat pattern (ex: spotted). The quantitative ones are those expressed in numbers, such as production traits (days of lactation, percentage of fat in milk, croup height). The expression of a production trait is determined by the action of several factors, classified as genetic and environmental. In breeding, environment is everything that is not genetic (climate, nutrition, hygiene, health, general management etc.). The term genotype is used to describe everything that is determined by genes. In addition to genotype and environment, there is another factor known as genotype-environment interaction. What would this factor be? In fact, the genome is like a box of Lego pieces. These parts can be used differently, as needed. That is, the genotype is expressed differently according to the environment in which the animal is. The genotype-environment interaction means that the full expression of the genetic potential of an animal is not observed when their genotype (genetic material) is in certain environments. Thus, in each environment the genotype will interact with the existing conditions and result in different phenotypes. Heritability seeks to measure how much of the variation in a quantitative trait is conditioned by genes. Imagine a completely standardized breeding condition, that is, all animals receiving exactly the same treatment (temperature, nutrition, everything the same). Any difference between individuals would be caused by genetic differences between them. In the real world, however, this does not happen. The environment always varies and interacts with the genotype. Thus, there is no certain and fixed heritability value, there is the heritability calculated for a population in a given environmental condition in a given time. In a country the size of Brazil, the environmental variation is enormous. Consequently, preserving the adaptability of the breed becomes a fundamental value, since changes in the environment can represent an additional expense in production.

Resistance to thermal stress

Over the past few decades, we have seen important environmental changes, with increased temperatures and prolonged droughts in some regions of Brazil. As a result, resistance to thermal stress, a characteristic present in Guzerá, becomes even more important.

To assess the response pattern of Guzerá cattle to thermal stress, we at the Federal University of Rondonópolis and Embrapa Dairy Cattle used historical milk production data on the test-day from the database of the National Guzerá for Milk Improvement Program and climatic data from the

National Meteorological Institute. The climatic variable used was the Temperature and Humidity Index (THI), obtained from the maximum daily temperature and humidity averages. It was observed that the increase in THI causes a reduction in the amount of milk produced. The impacts were -0.037, -0.019 and -0.006 kg of milk/day per unit of change in the THI, for the initial, intermediate and final stages of lactation. This suggests that the genotype-environment interaction can negatively affect milk production.

Heritability estimates ranged from 0.16 to 0.35 over lactation for different values of THI, suggesting the possibility of genetic gains with the selection for milk production at a given THI (environmental conditions of temperature and humidity) and obtaining animals more tolerant to thermal stress. The estimated genetic values for the Guzerá bulls in response to changes in the THI values varied month by month, confirming that the genotype-environment interaction due to thermal stress has an effect on milk production on the test-day. Despite the high dairy performance of Guzerá cattle under thermal stress, as verified in this study, the genetic trend, which evaluated the genetic progress that has occurred for milk production in function of the THI over the years, has shown a progressive reduction in heat tolerance. Therefore, new breeding strategies should be considered to avoid future negative impacts of thermal stress on milk production in Guzerá animals.

We need to improve Guzerá's productive performance without losing its differential in important traits such as adaptive ones, mainly because we are in the tropics, where the environment has extreme and even adverse conditions of temperature and humidity, and Guzerá is able to cope with them very well.

Does it make sense to make selection for milk and beef?

Some breeds proved to be good meat producers, or good milk producers, and others stood out with their double capacity: producing meat and milk (dual purpose). Animal specialization for the production of one or another product was a necessity to meet the growing demand of the world population for food. Genetic improvement tools have evolved, allowing selection based on the genetic values of animals for production to lead to a rapid increase in animal performance to produce meat or milk. Other breeders followed the path of jointly producing meat and milk, based on the potential of some breeds for dual purpose. This issue has always been controversial and many criticize the option of selecting meat and milk production characteristics at the same time, which goes against the specialization model of many countries. The research then decided to check whether this selection is indeed viable, to clarify and guide the breeders.

Guzerá is considered in Brazil as a Zebu breed of dual purpose and performance data on dairy and beef traits have been measured for years in several herds collaborating in the breeding programs of the breed. From this database, researchers and professors at the Department of Animal Sciences at the Federal University of Viçosa and Embrapa Dairy Cattle carried out a comprehensive study to estimate the genetic correlations between beef, milk and reproduction traits, using the database from the National Genetic Improvement Program of Guzerá for Milk and the Zebu Genetic Improvement Program.

The results were very interesting. Heritabilities, as usual, were high for beef traits and moderate for dairy traits, showing, as everyone knows, that direct selection for these traits is possible. The novelty was the genetic correlations between weight, dairy and reproductive traits, which were also favorable and allowed us to verify that, yes, joint selection is possible for these traits. The genetic correlations of weight at weaning, year and yearling with age at first birth ranged from -0.58 to -0.62 (that means, the greater the weight gain, the earlier the animal), showing that the selection for one

trait it will bring favorable and expressive changes in the other. The genetic correlation of weight at different ages with milk production in 305 days, which ranged from 0.25 to 0.36, also showed a favorable relationship between these traits, which allows direct or joint selection for gains in both traits. Likewise, the correlation of milk production in 305 days with age at first delivery was favorable (-0.14).

Therefore, in the Guzerá breed, there is no antagonism that makes concomitant selection for beef, milk and reproduction traits unfeasible. The option to specialize the breed for milk or beef, or to keep selection for both traits, is up to each breeder. Certainly, the genetic gains in each of these traits will not be the same as that of direct selection for only one of them, but it will be possible.

Somatic cell count (SCC)

Another study was carried out with the somatic cell count (SCC) of the milk from Guzerá cows. SCC is related to the occurrence of subclinical mastitis, which brings enormous economic losses to dairy herds. Thus, in order to estimate the relationship of somatic cell counts (SCC) with milk production traits, a study was conducted with the information available in the database of the National Genetic Improvement Program of Guzerá for Milk. In this study, it was found, first, that the average SCC in lactations was 214.5 ± 436.4 thousand cells/mL, a satisfactory average when considering the value of 500 thousand cells/mL defined by IN76 (MAPA, 2018) as the upper limit of quality milk for processing and consumption.

On the other hand, the estimate of heritability for SCC was low (0.08). Low heritability values for SCC have also been found in studies with other breeds. This indicates that SCC has a large contribution from the environment and a small contribution from genetics. This result is also good, because it is easier to improve sanitary management and adopt good hygiene practices for lactating cows than trying to make a genetic improvement so that the cows have less SCC and are more resistant to mastitis. The genetic gain would be small with direct selection to reduce SCC and, consequently, the occurrence of mastitis. On the other hand, the increase in SCC is a defense mechanism of the animal against the presence of infectious agents. As the immune system is closely interconnected, it would not be possible to reduce SCC in milk without affecting other aspects of the animal's defenses, with a great risk to the health of the herd.

In addition, practically null genetic correlations between the milk production traits and SCC were observed, indicating that it would not be possible to improve the SCC through direct selection for the productive traits. This was an initial study, which needs to be carried over with a larger volume of data and other tools and methods of genetic analysis for its definitive conclusion. We reinforce, therefore, that until now, environmental factors, such as adequate nutrition and hygiene when milking lactating animals, are the most important factors and must be worked on in herds to ensure the reduction of the occurrence of mastitis.

Future perspectives

The inclusion of Guzerá in the context of production efficiency and quality in the international livestock sector: How precision farming and phenotyping, together with systems biology, can assist in this process

Pablo Augusto de Souza Fonseca¹

¹Centre for Genetic Improvement of Livestock, Department of Animal Biosciences, University of Guelph, Guelph, ON N1G 2W1, Canada

The Brazilian agriculture has great international prominence, with Brazil being responsible for 8% of all world agricultural trade and making a fundamental contribution to the resources and raw materials to the sectors involved. The accumulated values in goods and services reached values around 200 billion US dollars, which corresponds to ~20% of the Brazilian Gross Domestic Product (<https://www.cnabrasil.org.br/cna/panorama-do-agro>). It is estimated an increase of 70% in the consumption of products of animal origin in 2050 due to the global population growth (FAO, 2009). In parallel, the international agricultural sector is going through a period of intense changes and the creation of new demands aimed at improving the quality of products, animal welfare and environmental care. Therefore, the development of methodologies, which allow the achievement of these demands, is a crucial step for the success and maintenance of the market.

Guzerá, because it is a dual-purpose breed, demands an even more caution due to possible correlations between traits, whether they are antagonistic or not. The investigation of the biological causes of this relationship between multiple traits should be prioritized in order to assist the more guided and specialized selection for traits of economic interest, as well as reducing the frequency of undesired responses in the selection process. However, to make this possible, a level of precision in measuring traits of interest, as well as an increasing in the frequency of measurement must occur.

In this context, precision farming/phenotyping is a strategic area for the sector. Data from precision phenotyping methodologies have gained considerable prominence due to the wide variety of information that can be obtained precisely. Sensors such as pedometers and collars equipped with accelerometers, imaging systems, and online phenotyping systems on automated milking platforms using proximal infrared (NIR) are clear examples of this technological diversity. The level of animal's activity, the time spent lying down, distinction and counting of feeding and ruminating events, breeding events etc., are examples of activities detectable by 3-axis accelerometers. This information can be integrated into statistical models for the prediction of events such as the number of days required for the animal to reach slaughter weight, feed efficiency calculations, detection of estrus events and detection of animals affected by health changes.

In swine and bovine, the use of image processing obtained using low-cost and non-invasive equipment, such as Kinect® (Microsoft, Redmond, WA), for the measurement of traits such as body weight, carcass yield, thermal stress, septic pododermatitis, behavior and reproduction have already been reported. This type of procedure can assist in optimizing the monitoring of growth, production and behavior of animals in a cost-efficient manner.

The recognition of animals through image and sound systems is also an extremely promising area. These systems may allow, in a near future, the replacement, or even the joint use, of radio frequency identification (RFID). The use of electronic earrings, although extremely useful, can present limitations and flaws when reading the signal emitted by the earring and data storage, which result in loss of information or inconsistent data.

Values such as total yield, percentage of protein and milk fat can be predicted and assessments such as somatic cell count and analysis of biomarkers for mastitis (beta-hydroxybutyrate) and meta-

bolic states, such as ketosis, can be performed using data from NIR and other biosensors on automated milking platforms. In addition, sensors internal to the animal, such as ruminal biosensors, can monitor changes in rumen temperature, pressure and acidity in a continuous and accurate manner, being extremely useful for assessing animal health and production levels. Finally, levels of hormones present in milk, such as progesterone, can be assessed. Consequently, the use of precision farming/phenotyping tools allows generating important information regarding the animal's reproductive status. Pasture assessment and herd monitoring through unmanned aerial vehicles (UAVs) and satellite systems can also strongly assist some sectors due to the common use of open feeding systems based on grazing.

These are just some examples of areas in which precision farming/phenotyping can act and assist the breed's production efficiency and quality. Precision farming has the main objective of increasing production efficiency as well as raising animal and human well-being through the application of advanced information and communication technologies, aiming at the use of resources and the precise control of the production process (BANHAZI et al, 2012). The variety of information generated through precision phenotyping methodologies, in a more homogeneous and high-yield system, can meet the demands present in the evaluation of traits of economic interest for the livestock sector. However, one of the main bottlenecks witnessed in the area of precision phenotyping is the selection of phenotypes with high precision and accuracy in the measurement, as well as the integration of several sources of information in a comprehensive system (GONZALEZ et al, 2018).

Bioinformatics and systems biology can assist in the identification of those phenotypes, which present greater evidence of biological contribution, when interpreting the results. However, it is necessary to weigh the cost / efficiency ratio of adding each of the phenotypes in breeding programs, in order to select those with greater efficiency in selection response and biological representativeness. Thus, it is essential to unravel the different levels of biological information, whether at the level of DNA, gene expression and its regulation, proteins involved in processes of interest, the metabolites generated and used in complex metabolic systems, or even the relationship between microorganisms and the host for production (for example, rumen microbiota and feed efficiency).

Despite its prominent position, the national livestock sector still produces below what its real potential is capable to produce. This can be explained by a reduced application of precision phenotyping technologies for measuring production characteristics, breeding schemes and advanced management strategies (VENTURA et al, 2020). The application of precision phenotyping and systems biology in the agricultural sector has the capacity to raise this potential and help the national livestock sector to better adapt to the current and future demands of the national and international market.

Introduction

The National Breeding Program of Guzerá Cattle for Milk (PNMGuL) is a joint program of Embrapa Dairy Cattle and the Brazilian Center for the Genetic Improvement of Guzera Cattle (CBMG²/ACGB). Several public and private bodies participate in this program, including semen processing centers, state research companies, the Federal University of Minas Gerais, the National Breeder and Researcher Association, breeders of purebred Guzera cattle, and collaborating farms that use the Guzera breed for crosses. The program received financial support from Embrapa, CBMG², ACGB, ABCZ, CNPq, Fapemig, the Ministry of Agriculture, Livestock and Food Supply, and Guzera cattle breeders.

This program is based on the integration of modern animal breeding tools to confer rapidity and reliability to selection and consists of three integrated information-generating schemes. The first consists of selection carried out by Guzera breeders on farms, who gather information on animals produced by directed breeding using non-selective official test-day milking records. The second, the Multiple Ovulation and Embryo Transfer (MOET) Nucleus, is a scheme characterized by conferring high intensity and rapidity to selection through the evaluation of offspring of cows that are genetically superior for milk production, multiplied by the transfer of embryos. The main goal of the Nucleus is the early identification of genetically superior sires for milk, which will be used directly in herds of the breed and in crosses. These sires can subsequently be included in progeny tests for reassessment and for obtaining additional accuracy. The evaluation of these young sires is based on the performance of their full sisters, paternal and maternal half-sisters, and other relatives. The third scheme is based on the productive performance of the daughters of progeny-tested sires produced by random mating. Although slower than the previous one, this method is the most accurate to evaluate the true genetic potential of a sire for milk production. The data originating from the different sources are genetically connected and are combined in a single archive, the database of Embrapa/CBMG²/NZA. The genetic evaluation for milk traits is therefore integrated, unique, and comparative.

Since Guzera is a dual-purpose breed, both the MOET Nucleus and various partner herds of the dairy breeding program also participate in the Genetic Evaluation Program of the Guzera Breed for Beef Production (PAGRG) of ANCP and GEMAC. Consequently, several sires are "double proven", i.e., they are genetically evaluated for dairy and beef traits. This summary reports for the 11th consecutive year the results of genetic evaluations of beef and reproductive traits in different proven sires for milk.

Conformation and management traits can help the breeder to obtain a herd with better production and economic efficiency. Several of these traits are being measured in the Guzera breed and this summary presents the evaluations of sires that met the accuracy requirements for some of them.

Molecular markers are promising tools that can be used complementarily in selection programs. Caution in the use of these marker in Zebu cattle is necessary since they are still being tested for validation. Since various molecular markers have already been studied in Guzera cattle, the genotypes of different proven sires are presented in the summary, particularly in an attempt to preserve some rare alleles and to assist in selection with due caution.

The economic importance of the different traits evaluated and presented in this summary varies widely across different niche markets and systems in which the breed is used. We decided to present the evaluations for the largest possible number of traits so that producers can choose those that are most appropriate and important for their particular objective and use reliable data in their selection work and breeding schemes. The main goal of the program is to generate technology and to produce

improved animals for production systems that take advantage of the qualities of Guzera cattle and their crossbreeds in order to obtain high production at low cost.

Traits Evaluated

Dairy traits

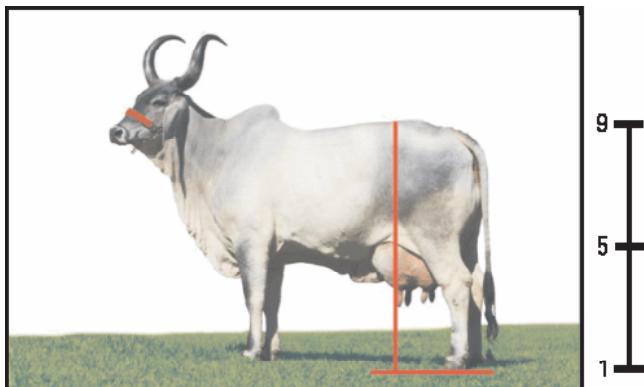

- **305-day milk yield:** the cumulative milk yield at 305 days of lactation. It should be noted that, if lactation has ceased before 305 days, milk yield regardless of the lactation length is assumed as 305-day milk yield.
- **Yield and content of fat, protein and total solids during lactation:** these are the main milk components whose yield is obtained by the laboratory analysis of milk samples collected from tested cows. Total solids, or dry extract, represent the set of milk components without water. Content is a way of expressing the relationship between milk yield and milk component yield in percentage units. The genetic correlation between milk yield and milk component yield is positive and, although high, is not equal to 1 or 100%, i.e., the increase in milk yield is always higher than the increase in milk component yield. Consequently, the genetic correlation between milk yield (kg) and milk component content (%) is negative. Thus, selection focusing only on milk yield may negatively affect the content of milk components.
- **Age at first calving:** the pursuit of reproductive efficiency of the herd is essential to ensure the economic viability of milk production. A cow that conceives at a younger age, i.e., that is precocious, has a longer useful life, reproducing more often in the herd and leaving a larger number of offspring and heifers necessary for replacement in the herd. The main economic consequence of reproductive precocity is the faster return on investment due to the increase in the milk volume produced during the period that cows remain in the herd. Hence, knowing the genetic potential of sires and dams for age at first calving is an important additional information for the genetic improvement of herds in which cows are late.
- **Milk production efficiency:** this trait is defined as the ratio between milk yield (kg) and age at calving (months). The trait reflects the early capacity of milk production of an animal and, indirectly, the economic return associated with the production costs of a replacement female in the herd. Milk production efficiency is also a preliminary indicator of useful life, i.e., it provides information about the probability of extending the productive herd life of an animal, reducing the risk of premature culling. Since it combines two traits, this information should be used when simultaneous selection for precocity and milk yield is desired, i.e., when both traits need to be improved in the herd. The positive expected progeny difference (EPD) thus indicates that the animal is able to leave daughters with a higher milk production potential at younger ages.
- **Response of breeding values for 305-day milk yield to the productive environment:** the breeding value of sires are estimated according the overall management level of the farms. The management level is determined based on the performance of the contemporary groups. This approach considers a genetically different response of animals to different environmental conditions (genotype x environment interaction). Sires whose response achieves reliability of 40% or higher for this trait are then classified as negative sensitive (-), positive sensitive (+), and robust (=). Negative sensitive (-) sires transmit to their daughters genes that favor milk production in herds of low management level (low input use, low-quality feed, basic general management).

Positive sensitive (+) sires transmit to their daughters genes that favor milk production in herds of high management level (high input use, high-quality feed, excellent general management). On the other hand, robust (=) sires transmit to their daughters milk production genes that are relatively indifferent to changes in the management level of the herds.

Conformation and management traits

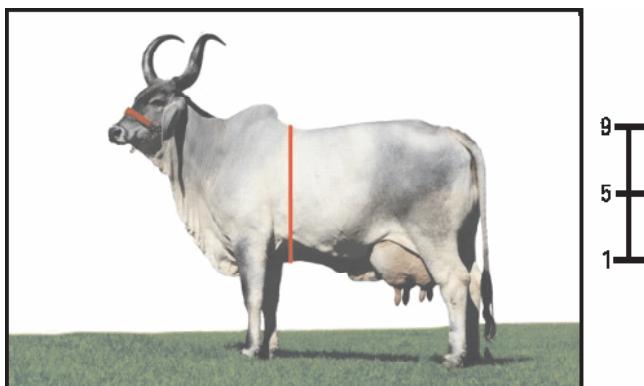

Morphological or linear type traits measured by the program were included according to their functional importance for survival, reproduction, udder health and animal production. So far, it was possible to publish the genetic evaluation for eight of these traits. The traits measured and figures illustrating the positions or sites where these linear measurements are taken are shown below for the traits that have already been evaluated genetically.

- Rump height

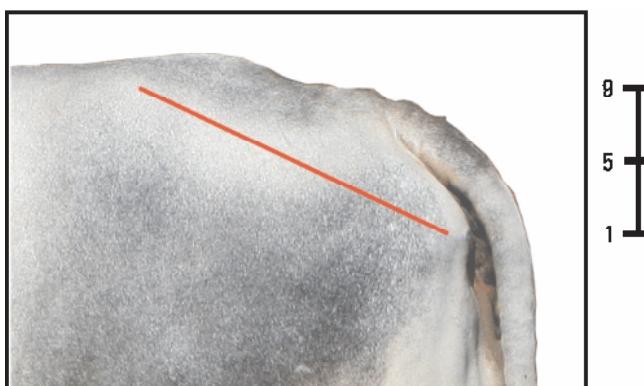

For this trait, it is desired that the hip is sufficiently high to keep the udder away from the ground.

- Heart girth

The heart girth is related to the cardiac, pulmonary and digestive capacity of the animal..

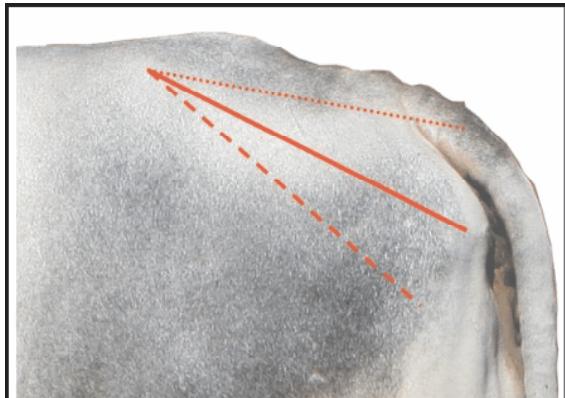

- Body length
- Rump length

This trait is related to dorsal support of the udder.

- Pin bones width
- Hook bones width

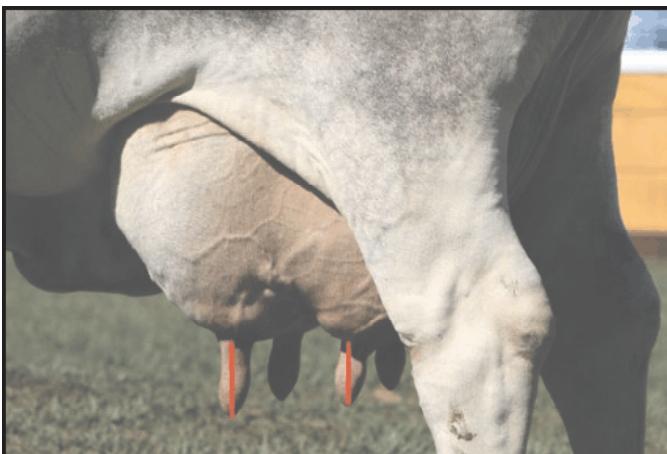

- Rump angle

It is measured by means of the inclination between pin and hook. A score above 5 indicates a drained croup and below 5, a flat rump. Extreme values (high or low) are undesired since they can cause calving problems.

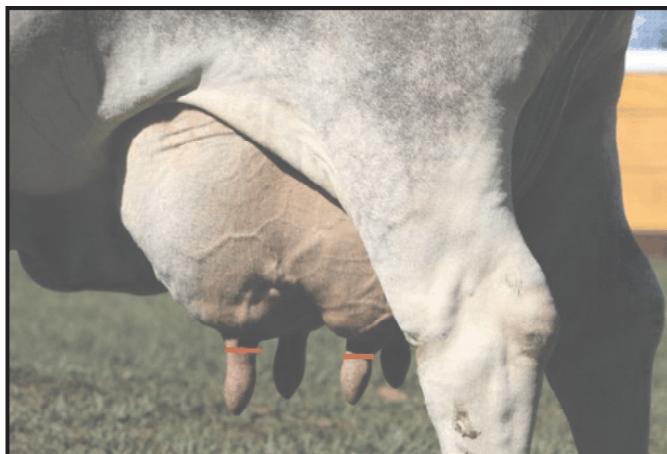

- Foot angle
- Rear legs (side view)
- Rear legs (rear view)
- Fore udder attachment
- Rear udder width
- Udder depth
- Teat length

The ideal teat length to facilitate milking is about 7.5 cm. Very long teats impair colostrum feeding by the calf, make milking difficult, and are related to an increased incidence of teat loss and mastitis. Very short teats are also undesired since they impair feeding and milking.

- Teat diameter

Teats with an intermediate to small diameter (3.8 cm) are desirable. Excessively thick teats impair milking and feeding and are therefore undesirable for the breed..

- Navel length
- Milking ease
- Temperament

This trait is related to docility and ease of handling of animals. Scores range from 1 to 5 and values close to 5 are desirable.

Beef and reproductive traits

- **Age at first calving (AFC):** This trait is an indicator of sexual precocity. Sires with negative EPDs (expressing fewer days to first calving) are desirable.
- **Gestation length (GL):** This trait has economic impacts since it is related to birth weight and calving ease. Negative EPDs indicate a shorter GL and smaller size of the calf at birth.
- **Scrotal circumference at 365 and 450 days (SC365 and SC450):** These traits show a favorable correlation with fertility and sexual precocity. Higher EPDs are associated with more precocious animals and higher fertility.
- **Weight at 120 days (W120):** This trait expresses the preweaning growth potential of animals. Higher EPDs indicate greater growth.
- **Maternal ability at 120 days (MA120):** This trait expresses the maternal ability of the cow during the preweaning period.
- **Weights at 365 and 450 days (W365 and W450):** These traits express the growth potential during the postweaning period. Higher EPDs indicate greater growth.
- **Mature weight (MW):** This trait is defined as weight from 4 to 12 years of age and is related to the maintenance costs and growth rate of the animal. Very high EPDs are associated with high maintenance requirements.
- **Accumulated productivity (ACP):** This trait indicates cow productivity in kg of weaned calves per year while the cow remains in the herd.
- **Rib eye area (REA):** An ultrasound-measured trait related to carcass yield. Medium to high EPDs are desirable.
- **Carcass finishing (ACAB):** Ultrasound-measured traits related to precocity and carcass finishing. High values indicate greater fat accumulation at these sites.
- **Longevity (STAY):** This trait, also known as stayability, expresses the ability of females to remain productive in the herd for a longer period of time. This EPD indicates the probability of a sire to leave daughters that stay in the herd up to 76 months of age and calve at least three times. Higher EPDs are preferable.
- **Percentile (TOP %):** This trait permits the breeder to rank the genetic material used in the list of animals evaluated. The values indicate the rank of the chosen animal within the percentage

range (from best to worst). Thus, a TOP 10% animal is located within the 10% superior animals for that trait.

Molecular Markers

Molecular markers are variations (or **polymorphisms** or **variants**) in the DNA sequence. They are the result of mutations and are common in all species studied. As a consequence, many genetic differences exist between individuals of any breed or species of interest. Some of these variations occur near or within the sequence of **genes** and may be used to investigate whether a certain gene influences any trait of interest, for example, milk production; hence, the term molecular marker. The variation is “marking” the region of interest that influences that trait.

There are two possibilities of how a molecular marker can influence any trait: 1) the variant directly modifies the function of a gene, or 2) the allele is located near another variant that modifies the function of the gene.

The majority of molecular markers developed so far has been described for taurine breeds. It is important to emphasize that great differences exist between taurine and Zebu breeds not only in their racial characterization, but also in their DNA. Thus, if a molecular marker was identified by “marking” a particular trait in one breed, the same marker may not “mark” this trait in another breed. Molecular markers must therefore be validated for each breed before they can be used in marker-assisted selection of genetically superior animals.

Kappa-casein: Kappa-casein is one of the coagulable proteins in milk. This protein stabilizes the casein micelles and determines the quality of the curd. During cheese production, kappa-casein is the main protein responsible for the retraction rate and clot firmness. In taurine cattle, allele **B** has been associated with more efficient clotting and higher cheese yields, which is the most desirable when the milk is destined for the cheese industry. This allele has also been associated with higher milk protein concentration.

Beta-casein: Beta-caseins form a group of highly polymorphic milk proteins. The A1 and A2 variants are the most common variants found in cattle herds. The A2 allele has been associated with higher protein content, lower fat content, and higher cheese yields. These proteins are also precursors of opioids produced by the animal itself. Opioids are substances that minimize the effects of animal stress. The A1 allele has been associated with autoimmune diseases, diabetes, heart diseases, autism, schizophrenia, and milk allergy in humans. The A2 allele is therefore considered the most favorable for human health.

Beta-lactoglobulin: Beta-lactoglobulin is a milk serum protein. In taurine breeds, allele **A** is related to higher milk production, higher protein content, and lower milk casein concentration. Allele **B** is associated with higher casein concentration, greater fat retention in the clot, higher thermal stability of milk, a higher dry matter content in cheese and, consequently, higher yields of industrial cheese. Thus, the “best” genotype depends on the destination of milk: allele **B** is more desirable if the milk is destined for cheese production and allele **A** if the milk is destined for milk production. It is important to maintain both alleles in the breed as a whole.

DGAT1 (K232A): In taurine breeds, allele **A** is associated with higher milk production, higher protein content, a lower content of trans fats, and a higher content of unsaturated fats (healthier). This allele is also associated with lower intramuscular fat deposition (marbling) in the carcass. On the other

hand, allele **K** is associated with lower production of milk with a higher fat percentage and a higher degree of marbling in the carcass.

Thyroglobulin: This protein is a precursor of thyroid hormones that regulate the metabolism, growth and development of animals, including the development of the mammary glands. Studies suggest that animals carrying the **T** allele have greater intramuscular fat deposition and consequently a higher degree of marbling in meat.

Prolactin: This hormone regulates mammary gland development and the onset and maintenance of lactation, as well as milk production. In addition, prolactin influences the activity of genes that encode milk proteins. Genetic variants have been identified in the prolactin gene, which affect variations in milk production and composition. One of these gene variants produces the AA, AG and GG genotypes.

Concepts

Expected progeny difference (EPD) (or predicted transmitting ability): This measure describes the transmission of the genetic potential from a given animal to its offspring and is expressed as the measurement unit of the trait (e.g., kg for milk and weight, days or months for age at first calving). It has a positive or negative sign in relation to a given genetic basis. The EPD is measured based on the expected performance of the sire's daughters in relation to the basis used and is therefore an estimate of half the breeding value of a sire. For example, an EPD of 300 kg for milk yield indicates that, if the sire is used in a population with a genetic level equal to that of the basis, his daughters will produce an average of 300 kg per lactation more than the average of the herd where they produce. Considering two sires, one with an EPD of 300 kg and the other with an EPD of -100 kg, it is expected that in random mating the daughters of the first sire produce an average of 400 kg more than the daughters of the second sire (given that they are contemporaneous herd-mates).

Standardized expected progeny difference (or standard transmitting ability, STA): This measure refers to the standardized EPD of a trait, i.e., instead of being expressed as a measurement unit (kg, cm, days, months, etc.), it is expressed as standard deviation units from a normal standard curve. This transformation is done to facilitate visualization and comparison between traits measured in different units. For example, presentation of the EPDs for traits such as milk and fat yield, expressed in the same unit (kg), in the same graph will be very difficult because of the difference in values (+300 kg vs +10 kg). The inclusion of other conformation traits in the graphs, expressed in different units (cm or scores from 1 to 9), is practically impossible. Thus, the logical solution for combining several traits in the same graph is to standardize each of them so that all traits can be presented in the same standard graph. Standardization is obtained by dividing the EPD of the sire by the standard deviation of the EPD of the trait obtained for sires evaluated for conformation and management. The STA thus allow us to know the deviations of the same sire for different traits.

When STA is used, the variation is the same for all traits, while the same is not observed for the variation of EPDs. Thus,

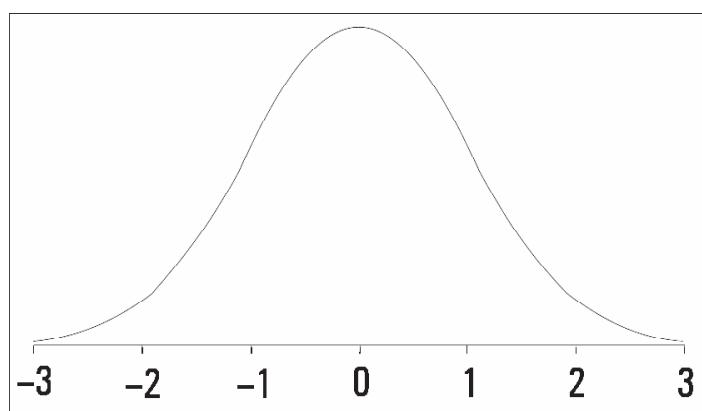

Figure 1. Distribution of standard transmitting ability (STA).

68% of the STA values are between -1.0 and +1.0 for any trait; 95% are between -2.0 and +2.0, and 99% are between -3.0 and +3.0. Figure 1, called “Distribution of standard transmitting ability”, is also called a “standard normal distribution” or bell-shaped curve.

Many traits, including production traits, can be represented in this way. In this curve, information for most sires are found at the midpoint (STA = 0). As the value of STA deviates from the average (either to the right or to the left), there are progressively fewer sires. Only 1% of the sires are found at the extremes (-3.0 and +3.0). At point zero, the STA represents the average of the breed for that trait. Knowledge of a sire's STA permits to predict how far will be his offspring from the average.

Genetic basis: The genetic basis is assumed to be “zero”; above this values, animals are classified as positive and, below this value, as negative. As a rule, it is an arbitrarily chosen reference that meets coherent and practical technical criteria, which facilitate the understanding and reasoning of producers for their selection work. The genetic basis can be fixed or flexible. In the case of dairy, conformation and management traits, the genetic basis used is the average of the breeding values in the year studied, i.e., a flexible basis. The genetic basis used in the evaluations of beef traits is formed by founder animals, i.e., those without information from ancestors. Thus, animals with average values for dairy traits in a given year and animals without ancestor information about beef traits have a zero EPD.

Heritability: It is a measure of the degree to which a sire or cow is able to genetically influence the expression of traits in their offspring. Greater genetic progress can be achieved for traits that are more heritable. Consequently, for the same selection intensity, much greater genetic progress is expected in matings involving highly heritable traits. Not only the heritability of a trait but also its economic importance in relation to overall economic performance must be taken into account when choosing traits to be included in a selection program. Consequently, breeders can concomitantly change production averages and increase the economic efficiency of the herd for these traits.

Accuracy or reliability: This is a measure of association between the estimated breeding value of an animal and its true breeding value. The higher the reliability, the greater the confidence that must be placed in the estimated breeding value of the animal. The degree of reliability depends on the amount of information used to evaluate the animal, including data of the animal itself, its daughters and other relatives, and on the distribution of these data in different environments or herds. In addition, the heritability of a trait is related to the reliability of the information about the animal. High heritabilities of a trait indicate that the information of the individual itself is more reliable for estimating its breeding value. On the other hand, low values indicate the need of including information from relatives in the estimation of breeding values of individuals to improve reliability.

Average coefficient of relationship (AR): This coefficient is an estimate of the genetic relationship between individuals (animals) of a population because they have one or more common ancestors, i.e., they are related. This information reflects the intensity at which each individual contributes or has contributed genetically to the population and permits to describe its dynamics and structure. Together with knowledge of the inbreeding coefficient (consanguinity), the CR is of great practical utility by assisting in the appropriate selection of animals for breeding in the herd, in minimizing inbreeding and its undesired consequences for the population such as the loss of genetic variability, and in identifying lineages of interest for preservation. High CR values indicate that the individual (sire or dam) has been widely used in the population and that the chance of the sire/dam mating with a relative in this population (herd) is very high. Small or zero values do not necessarily indicate that the individual is little related or unrelated to the population, as they may reflect the lack of knowledge of its complete genealogy or origin (founders and ancestors).

Response to the production environment: This measure represents the expected performance of daughters of a sire in a given management environment (environmental gradient), from more to less intensive, in terms of the adoption of technologies, infrastructure, diet, hygiene practices, grazing regime, confinement, etc. The results of this assessment are presented in an easy visual manner. Sires will have only one management column filled out in the case of prediction of satisfactory performance of their offspring in only one management condition (low or high). In the case of prediction of satisfactory performance of their offspring in all managements, i.e., regardless of whether the management is high or low, both management columns will be filled out. See the diagram shown in Figure 2.

Sire's Name	Sire's identification	Environmental gradient*		Reaction**
		Low-input management	High-input management	
Fulano do Zebu	ZEBU1			SENSITIVE (-)
Sicrano do Zebu	ZEBU2			SENSITIVE (+)
Beltrano do Zebu	ZEBU3			ROBUST (=)

*Environmental gradient: Classification of the management level or pattern

****Reaction: sensitive (-) = underdemanding animal in environmental conditions, i.e., able to produce in simple environments (low-input management); sensitive (+) = overdemanding animal in environmental conditions, i.e., able to produce in refined environments; Robust (=) animal able to produce in any environment, unregardless of the environment pattern.

Figure 2. Schematic representation of the response to the production environment

Genetic Evaluation

Every selection process implies differential reproduction, with greater multiplication of genetically superior animals and lower multiplication of inferior animals. Thus, the starting point for any selection process is the estimation of the animals' breeding values for decision-making on reproduction and culling. Genetic evaluation comprises a series of statistical analyses that allow us to assess the breeding value of animals, a factor that, together with environmental effects, determines the animal's phenotype. Genetic evaluations of milk production traits, in particular, permit to estimate the breeding value of animals from their own phenotypes in cases of females and/or from ancestors (mother, grandparents), collaterals (sisters, cousins) and offspring in the case of females and males.

Methodology

The mixed model methodology permits to obtain best linear unbiased predictions (BLUP) of breeding values based on the EPDs of each animal for the different traits measured. The BLUP animal model used in these evaluations is a modern and robust method that produces EPD estimates based on the performance measures of each animal and its relatives, ancestors, collaterals and offspring included in a relationship matrix. In this assessment, all relatives of an animal identified affect its evaluation. Similarly, each individual influences the evaluations of its relatives. The level of influence depends on the degree of relationship between individuals. Offspring, parents and full-sibs (same father and same mother) exert a greater effect on the evaluation of the individual than grandparents, half-sibs, cousins, uncles, and other more distant relatives.

Dataset, Methodology and Analyses Used in Genetic Evaluations

For genetic evaluation, all lactations at first calving and lactations up to the fifth order were considered given that the first test-day lactation of the cows had terminated due to natural causes. Ongoing lactations lasting more than 140 days were extrapolated to 278 days (average lactation length in the breed) using adjustment factors of the breed and considering the time of calving and average yield of the herd.

To estimate the genetic capacity of an individual, the environment where the cow produced must be taken into consideration, for example, the year and season of calving. Thus, the allocation of test sires to several herds is important so that the performance of their offspring is evaluated under different environmental and management conditions. The offspring of the sires evaluated are therefore distributed across the southeast, northeast, and mid-west regions of Brazil. In addition, their milk production should be adjusted for the effect of age at calving to permit the comparison of cows. For this purpose, milk yields are standardized for two milkings and at 305 days of lactation. Adjusting for non-genetic factors or effects will permit to obtain reliable estimates of the genetic merit of the animal.

The data used originated from **141** herds (**76** purebred and **65** crossbred) participating in the NZA, progeny testing, and MOET Nucleus. The progeny test already includes **200** sires divided into **21** groups that represent the existing genetic lineages in Brazil. The offspring of the sires evaluated are distributed across the southeast, northeast and mid-west regions of the country. In this year, the first-lactation milk yields of offspring of sires from the first to the **17th** group were evaluated. From the MOET nucleus, information of **182** families derived from elite donor cows was used, whose offspring completed their first lactation under standardized conditions on the Taboquinha farm, which hosts the nucleus. The age at first calving data used were obtained from **125** herds (**64** purebred and **61** crossbred) participating in the NZA, progeny testing, and MOET Nucleus.

In this year, milk yield records from **19,485** lactations of **11,821** multiparous cows were initially analyzed. After depuration, **13,698** lactations were used in the genetic evaluations, including 9,204 first-lactation records of **79%** purebred cows and **21%** crossbred cows. Data from **13,698** lactations were used for the genetic evaluation of milk production efficiency. For age at first calving, records of **8,978** lactations were analyzed, **81%** from purebred cows and **19%** from crossbred cows.

The statistical model used for genetic evaluation of the animals included the fixed effects of herd-year of calving, season of calving, breed composition of the sire's daughter, and age of cow at calving. In addition to the error, the effect of the animal (cow, sire, and dam) and of the environment were included as random effects. The genetic evaluations of fat, protein and total solids yields were performed in two-trait analysis with milk yield as anchor trait using animal model procedures. The data were analyzed using the MTDFREML package, which evaluates an individual under an animal model and estimates variance components using the derivative-free restricted maximum likelihood (DFREML) method. A complete relationship matrix that included **28,475** individuals was added for the prediction of the breeding values or EPDs of each animal. The heritability of milk yield was **0.30 ± 0.003**. The genetic basis used, estimated to be zero, corresponds to the average breeding values of all animals evaluated (males and females). The heritability of milk production efficiency was **0.51 ± 0.023**. The heritability of age at first calving was **0.13 ± 0.022** using the complete relationship matrix.

The overall means of the traits evaluated based on the PNMGuL database are reported below. The average lactation length was **283 ± 67** days. The average 305-day milk yield in the Guzera database, adjusted for mature age, was estimated at **2,466 ± 1,298** kg. The average production were **95 ± 46** kg for fat, **67 ± 32** kg for protein, and **242 ± 110** kg for total solids. An average fat content of **4.4**

$\pm 1.1\%$, protein content of $3.2 \pm 0.6\%$, and total solid content of $12.0 \pm 2.0\%$ were obtained. The average milk production efficiency was 45 ± 28 kg/month. The average age at first calving was 44 ± 9 months ($1,339 \pm 274$ days), ranging from **24 to 71** months (**731 to 2,161** days)

Analysis of the response to the production environment is the result of a partnership between Embrapa Dairy Cattle and the Animal Breeding Group at the Federal University of Rondonópolis – GMAT/UFR. The database used for this analysis consisted of 41,782 test-day milking records from 5,663 first lactations of purebred Guzera cows. The reaction norm approach was used to determine the response of breeding values for 305-day milk yield to the production environment, which is well described and consolidated in the scientific literature. In the second step of analysis, this approach permitted to obtain the breeding values of animals as a function of the effects of contemporary groups derived by the conventional BLUP procedure in official genetic evaluation. Once the solutions of the contemporary group effect were obtained by the conventional BLUP procedure, a reaction normal model was fitted to the data. The same effects as used in the model of official genetic evaluation were considered in the reaction norm model, which only differed in terms of breeding values that were regressed on the solutions of the contemporary group effect.

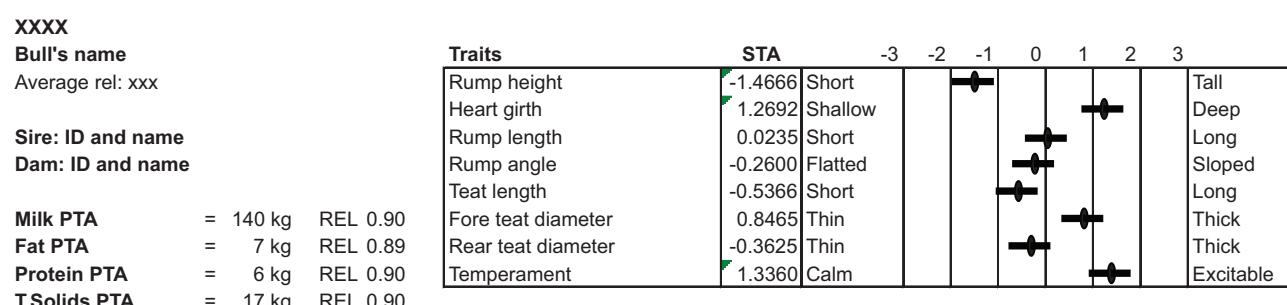

Table 1 shows the overall means of the conformation and management traits and their respective STA and heritability. The figures illustrate the results of the linear evaluation system obtained for sires that had at least five daughters measured in order to ensure higher accuracy of the estimates.

Table 1. - Overall means of the conformation and management traits evaluated by the linear system and their respective STA and heritability..

Traits	Mean	STA	h^2
Rump height	143.5	< 0.00	0.43
Heart girth	180.1	0.04	0.29
Rump length	43.1	0.08	0.24
Rump angle	26.0	-0.03	0.11
Fore teat diameter	3.8	-0.07	0.17
Rear teat diameter	3.4	-0.01	0.28
Teat length	7.3	0.14	0.25
Temperament	2.2	-0.02	0.29

The following illustrates the presentation of the results for the different traits using STA. The first column, "Trait", shows the names of the traits and the column "STA" reports their predicted standardized capacity of transmission. The line in front of each trait indicates its confidence interval, a measure related to the mean and reliability of the STA estimate. The point above the line corresponds to the STA estimate and the length of the line to the confidence interval, i.e., the shorter the line, the higher the reliability of STA, and vice-versa. It also indicates the expected extent to which the average STA estimates in future matings will be within those limits in 95% of cases (Figure 3).

Figure 3. Example for interpretation of the results.

It is important to note that these data should be used as complementary information in the matings. Deviations of the conformation and management traits to the right or left indicate genetic progress in the chosen direction. For example, if a cow has very large teats (above the average), it is desirable to expose her to a sire with a negative STA for teat length in order to correct this defect in the future generation. However, if the cow has very small teats, the desirable will be exposing her to a sire with a positive STA. The same logic applies to the other traits.

The database possesses approximately 291,000 weight records, 53,000 records of scrotal circumference, and 54,000 animals are registered in the relationship matrix, which belong to 79 herds evaluated. In addition to animals for dairy cattle evaluation, this database also include animals for exclusive evaluation of beef traits.

The EPDs are estimated by the mixed model methodology under an animal model, which allows to use all available information of the animal (pedigree, own performance and that of its parents), as well as to obtain the best non-biased predictors (BLUP) for all EPDs. Accuracy is calculated following the norms of the Beef Improvement Federation (BIF), which indicates the relationship between the estimated and the true breeding value of each animal, i.e., it is related to the degree of confidence in the EPD.

The single-step genomic BLUP method (ssGBLUP) is used for this evaluation, employing a multitrait animal model. The method permits the inclusion of molecular data in conjunction with all available information on the animal. In ssGBLUP, all molecular markers and phenotypic data of genotyped and non-genotyped animals are considered simultaneously, permitting their inclusion in the prediction of genomic breeding values for direct and maternal effects for all animals involved in the analysis, with or without a production record.

The following table shows the equivalence of true accuracies (used in the dairy evaluations) and BIF accuracies (used in the beef evaluations).

Table 2. Equivalence of Real and BIF reliabilities - (%).

Real (%)	15	20	25	30	35	40	45	50	55	60	65	70	75	80	85	90	95	99	100
BIF (%)	1	2	3	5	6	8	11	13	16	20	24	29	34	40	47	56	69	86	100

Results of Genetic Evaluation

Table 3 shows the results of genetic evaluation of milk yield, age at first calving and milk production efficiency for the groups of sires undergoing progeny testing, young sires of the MOET Nucleus, and sires whose data on the production of their daughters are included in the database of Embrapa/CBMG²/NZA. This publication includes only sires that, when evaluated by progeny testing for milk production, had a reliability greater than 0.50 and first-lactation daughters in at least three herds that, when evaluated based on their siblings in the MOET, also had a reliability greater than 0.50 and at least one full-sib with lactation measured in the nucleus.

Table 4 shows the results of new sires and MOET families included in the 2021 genetic evaluation.

Table 5 shows the results of genetic evaluation of yields and content of fat, protein and total solids for the groups of sires undergoing progeny testing, young sires of the MOET Nucleus, and sires whose data on the production of their daughters are included in the database of Embrapa/CBMG²/NZA.

Table 6 shows the genotyping results of some genetic markers for Guzerá breed sires.

Table 7 shows the results of genetic evaluation of cows used in the genetic evaluation of sires up to the fifth lactation given that they had been evaluated in the first lactation, obtained in the habitual management of the farms in contemporary groups within the minimal requirements of the program, i.e., three contemporaneous cows of at least two sires.

Table 8 shows the results of genetic evaluation of Guzera sires for milk production according to the management level of the herds, i.e., the response to the productive environment.

Table 9 shows the results of the performance of double proven sires in genetic evaluations for growth, carcass and functional traits.

Table 10 shows the results of the performance of double proven sires in genetic evaluations for reproductive traits.

Table 11 shows the partner farms of purebred cattle.

Table 12 shows the partner farms of crossbred cattle.

Table 13 shows the batteries of sires in the progeny testing.

Table 3. Results of genetic evaluation for milk yield, age at first calving (AFC) and milk production efficiency (MPE) in the progeny testing (PT), MOET Nucleus and NZA performed in 2021 and coordinated by Embraça/CBMG².

*Environmental gradient: Classification of the management level or pattern

****Reaction: sensitive (-) = underdemanding animal in environmental conditions, i.e., able to produce in simple environments (low-input management); sensitive (+) = overdemanding animal in environmental conditions, i.e., able to produce in refined environments; Robust (=) animal able to produce in any environment, unregardless of the environment pattern.

General information about the Guzera Breeding Program

Presidents of CBMG²

Bernhard Winkler (1992-1994)
Eduardo Almeida (1994-1996)
Bernhard Winkler (1996-1997)
José Orlando Duarte (1997-1998)
Roberto Winkler (1998-2002)
Virgilio José Matias Melo (2002-2006)
José Henrique Diniz Figueiredo (2006-2008)
Ariane Maria Figueirêdo Menicucci (2008-2016)
Carlos Fernando Fontenelle Dumans (2016-2020)
Paulo Roberto Menicucci(2021-actual)

Researchers and Technicians of the Involved Public Institutions

Andrea Alves Egito - Embrapa Gado de Corte
Anibal Eugênio Vercesi Filho - IZ/SP
Fabyano Fonseca e Silva - DZO/UFV
Humberto Tonhati - FCAV/UNESP
José Aurélio Garcia Bergmann - EV/UFMG
Júlio Cesar Carvalho Balieiro - FMVZ/USP
Lenira El Faro Zadra - IZ/SP
Luiz Antônio Framartino Bezerra - ICB/USP
Maria de Fátima Ávila Pires - Embrapa Gado de Leite
Maria Raquel Santos Carvalho - ICB/UFMG
Mario Luiz Martinez - Embrapa Gado de Leite (in memorian)
Paulo Sávio Lopes - DZO/UFV
Pedro Alejandro Vozzi - CTAG/ANCP
Raimundo Nonato Braga Lobo - Embrapa Caprinos e Ovinos
Raysildo Barbosa Lobo - ANCP
Roberto Luiz Teodoro - Embrapa Gado de Leite
Ricardo Vieira Ventura - FMVZ/USP
Vânia Maldini Penna - CBMG²

Breeders and/or Owners of the Animals Chosen to the Dairy Breeding Program (sires and dams, progeny testing and MOET Nucleus)
