REPORT ON PRESENT STATUS OF *Hevea* GERMPLASM IN BRAZIL
COLLECTED IN 1981 IRRDB EXPEDITION
18 JUNE - BRASILIA - BRAZIL

INTRODUCTION

The first expedition with the purpose of collecting botanical material of native rubber trees (*Hevea* spp) in Brazil was held in 1945 in the Rondonia Territory. The collected seeds were planted in 84 hectares but these were destroyed by fire in 1950. Later in 1952, a new expedition was designated to collect materials from the same trees in the same area (Moraes 1963). Ten years later, in 1962 a further expedition was carried out and a *Hevea* breeding programme based on the wild mother trees in jungle was initiated. From the results of previous expeditions, the Acre and Rondonia states have shown the presence of high yielding vigorous germplasm.

In 1974, SUDHEVEA carried out with IRCA an expedition in Acre and Rondonia for collecting budwood. Those budwoods were sent to Belem. Later these materials were multiplied and sent to a quarantine station in Guadalupe. So, in 1978, 41 clones were introduced in the Ivory Coast.

In 1978, IRRDB decided to organise a series of expeditions to cover the whole Amazon basin. Thus the first phase of the joint IRRDB/Brazil expedition was carried out successfully from January to March 1981. The main objective of this mission was to collect seeds, budwood and seedlings of *Hevea* spp from Acre, Rondonia and Mato Grosso areas. A total of 64.723 seeds and about 1.522 meters of budwood were collected.

All the seeds and budwood collected were sent to the National Rubber and Oil Palm Research Centre (CNPSC) in Manaus. The seeds were examined for presence of pathogens and viability and divided into two equal portions: 50% were planted in CNPSC. From the 32 thousands seeds, 23.235 seedlings

have been obtained. These seedlings were raised in nursery in the distance of 1.0 x 1.0 meter and were released for establishment in the field since February 1982.

In addition to the seedlings, budwood of 194 mother trees have been multiplied in the primary nursery in Manaus.

This report presents, details of the grafted germplasm at CNPSD, as to inform the situation of this material and the availability of the material for dispatching to the Intermediate Quarantine Nursery in Guadalupe.

I - BACKGROUND OF THE MOTHER TREE BUDWOOD COLLECTION

a) Selection

In the pre-selection of trees in the field, the basic objective was to identify the best yielding phenotypes for further yield recording and observation. The findings from the preliminary investigations have been used in the process.

b) Method for collecting

For the pre-selection of the wild mother trees, the tappers were contacted for location of the high yielding trees giving more than 1000cc of latex per tapping. This information was confirmed. Absence from *Microcyclus ulei* and *Phytophthora* sp leaf fall symptoms was checked visually. Budwood from orthotropic branches were then collected and the cut end waxed and stored in moist saw-dust and sent for grafting at the CNPSD's nursery in Manaus.

c) Mother tree collecting data

Yield, number of panels, circumference at 1,5m of height and

degree of disease incidence were recorded for each selected tree. Bark samples were taken for laboratory analyses. The bark samples were taken at precisely 1.5m above the soil surface.

d) Bark characteristics measurements

The following bark characteristics were measured:

1. Bark thickness
2. Total number of latex vessel rings was determined by examining the radial longitudinal sections of the bark.
3. Diameter of latex vessels was observed in the transverse section of the bark.
4. Density of latex vessels per 5 mm of ring was determined taking into account the average per all rings.
5. Average distance between consecutive latex vessel rings was determined based on all rings.

The results of these measurements can be followed in Table 1.

II- CURRENT STATUS OF THE MOTHER TREES BUDWOOD

A total of 194 mother trees budwood collected was originated from Rondonia (118) Mato Grosso (49) and Acre (27). Budwood of all mother trees were multiplied in the primary nursery at CNPSD experimental field. Among these total only 155 had been survived in budwood nursery. At the present the material are distributed as follows:

	<u>Clones with budwood</u>	<u>Clones with dormant budstumps</u>	Total
Rondonia	86	05	91
Mato Grosso	43	00	43
Acre	21	02	23
Total	150	07	157

The possible cause of the insucces of same clones were the quality of the budwood collected, no peeling etc.

Budwood of each survived genotype was supposed to be released to Guadalupe on February 1982 and additional shipment of budwood to Guadalupe was planned for April of the same year. Nevertheless, the slow growth of some clones and the high incidence of *Thanatephorus cucumeris* which was difficult to control because the heavy rain on the period of January - March retarded releasing of the material for September or October of the current year.

a) Disease Control

The grafted nursery has been sprayed twice a week with fungicide, against *Microcyclus ulei* and *Thanatephorus cucumeris*. Therefore, the frequent rains washed off the leaves, making it difficult to control the *T. cucumeris*. Depending on the weather conditions, the new leaf whorls were completely defoliated.

The incidence of *T. cucumeris* as well as the severity of the infection of the disease is strongly influenced by the prevailing climatic condition.

b) Variation of the clones in the nursery

Great inter and intraclonal variability has been observed among the different materials, mainly growth. It is possible that the main factor is related to soil, as we know, some soils of Rondonia and Acre have high fertility and high pH. The soils of Manaus have low fertility and low pH. Similar performance of materials selected in both states in 1974, 1978 and 1979 prospections have been observed in Manaus. Emphasis should be done to the trees selected in Costa Marques in Rondonia where it is suppose to be a overlapping area of two species of *Hevea*. Probably *H. brasiliensis* x *H. guianensis* hybrids. General aspect concerning grafting and growth of the clones can be followed on Table 2.

III - CURRENT STATUS OF SEEDLINGS MATERIAL COLLECTED IN 1981 PROSPECTION

1. NURSERY STAGE

The viability of the seeds planted in Manaus had raised about 20.000 **seedlings** in the nursery originated from 61 different provenances (**Table 3**).

The nursery was located at the experimental field of the Rubber Research Centre (CNPSD). The seeds were germinated at seedbed and planted at the nursery. The spacing used was 1.0 x 1.0 meter and was remained in the nursery for a period of 12 months.

a) Girth measurements

On February 1982, a total of 20 thousand seedlings were girth measured in the nursery at the height of 20cm from the ground. All the data was recorded on the CNPSD computer for future needs.

b) General disease observation

For growth development, fungicide against *Microcyclus ulei* and *Tanathephorus cucumeris* was sprayed. Nevertheless the fungicide was not effective against *T. cucumeris* during the most critical rain season (January - March). *M. ulei* was not severe, during the nursery period.

2. FIELD

The seed collected in the 1981 prospection were established as Provenance blocks and Provenance trial. The seedlings were cut back and transplanted in the field as mini-stumps on April 1982.

Provenance blocks

The size of the blocks varied according to the number of the seedlings for each different provenance. The field planting was carried out at a spacing of 4.0 x 4.0 meters and comprehended an area of 10 hectares.

Provenance Trial

In addition to the blocks, a experiment designed as 6 x 6 triple lattice, 50 trees per plot, spaced 4 x 4m was established. The experiment titled "Study of genetic variation among different provenance of *Hevea brasiliensis* is 9 ha big and has the following objectives:

- To identify genetic differences concerned to primary and secondary characters associated to the provenances.
- To identify the magnitude of the geographic variation estimated by the difference among provenance.
- To select the best individuals among the better provenances.
- To investigate the variability in relation to the incidence of deseases including the most susceptible among the different provenancœs.

Evaluation

During the first phase (seedling nursery) only diameter and height growth were recorded. All these data were recorded at CNPSD computer for the future needs.

During the second phase (adult seedlings) after tree years, numerous characters will be documented following the descriptors manual that include besides primary and secondary characters, other characters.
